

Long-term solar activity: Knowns and unknowns

Ilya G. Usoskin

University of Oulu, Finland

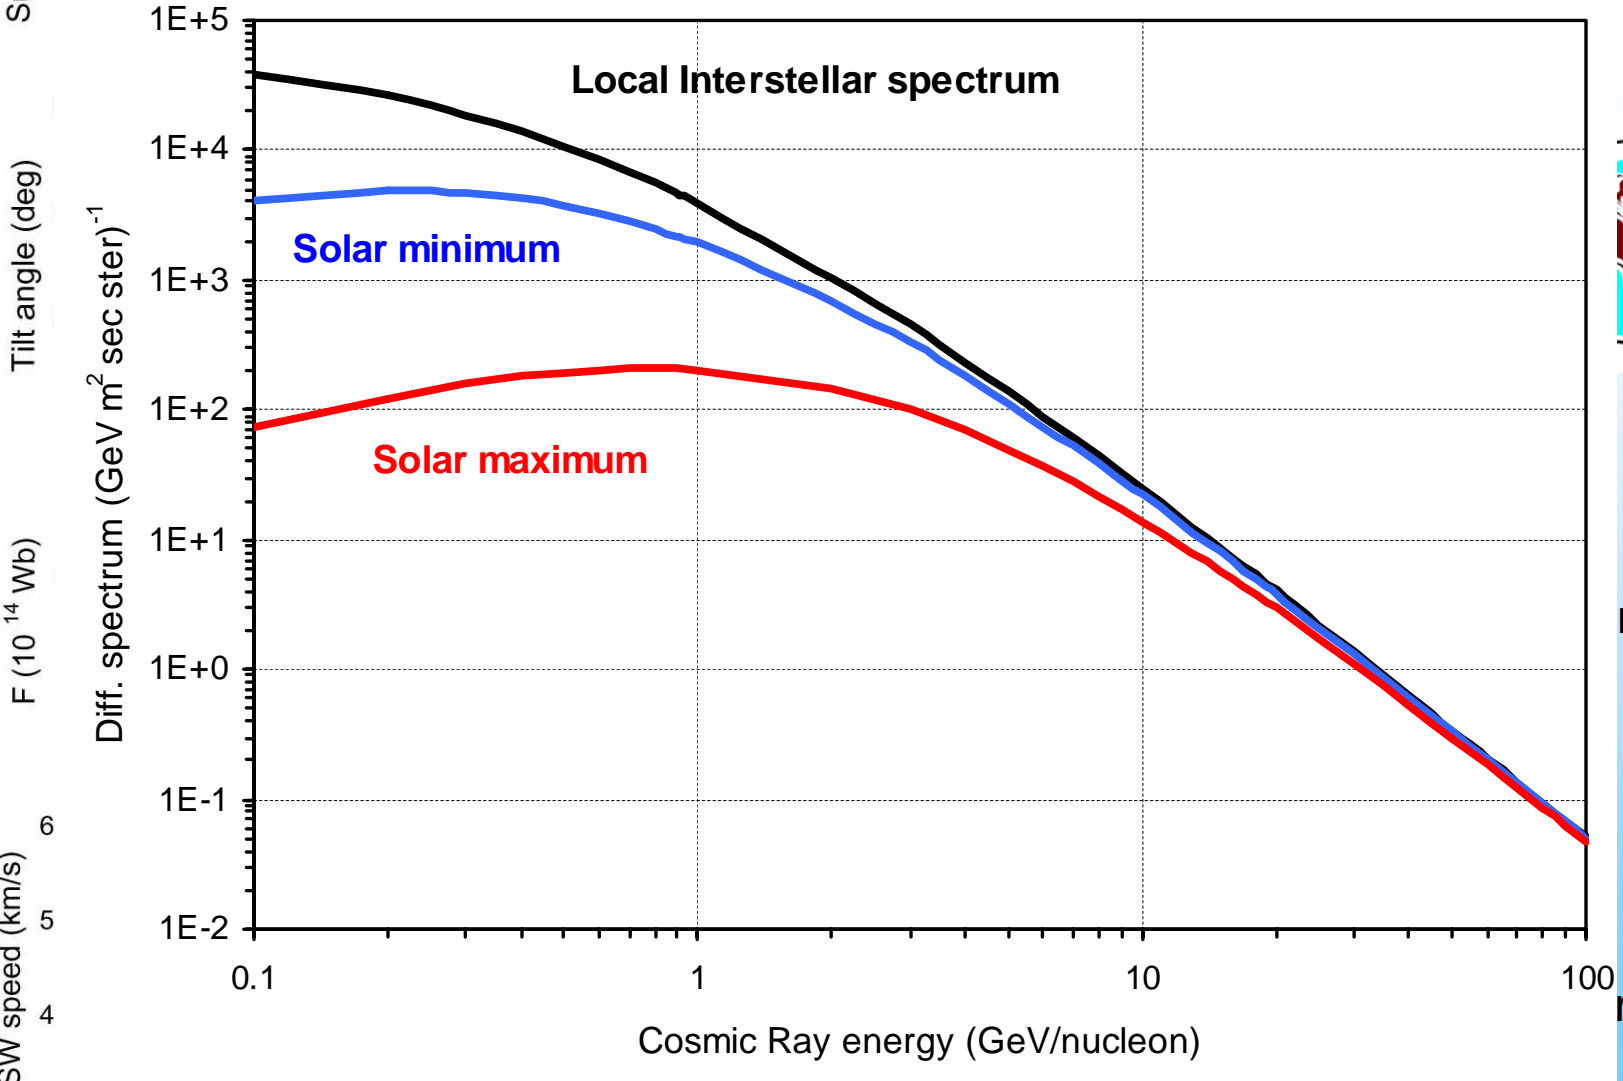

History

Solar activity changes

- 11-year solar cycle (Christian Horrebow – 1770s; Schwabe – 1843)
- Variable amplitude/envelope (Gleissberg – 1944);
- Maunder minimum (Hivelius; Eddy –1976);
- The contemporary level was high but is lower right now;

- Variable solar wind speed, interplanetary magnetic field, interplanetary magnetic field, interplanetary magnetic field
- Galactic cosmic ray modulation
- Geomagnetic shielding of cosmic rays

netic

ming

solar cycle variations

- 11-year cycle due to solar activity
- Weak 22-year cycle due to charge-dependent drift effects
- short-term fluctuations.
- Centennial variability?

Cosmogenic isotope production

Atmospheric cascade

In the atmospheric cascade, nuclear reactions may take place, most important being:

Spallation reactions on O, N, Ar \rightarrow ^7Be , ^{10}Be , ^{22}Na , ^{36}Cl , etc.

Neutron capture: $^{14}\text{N}+n \rightarrow ^{14}\text{C}+p$

Storage in natural independently dated archives: ice-cores, tree trunks, sediments, corals

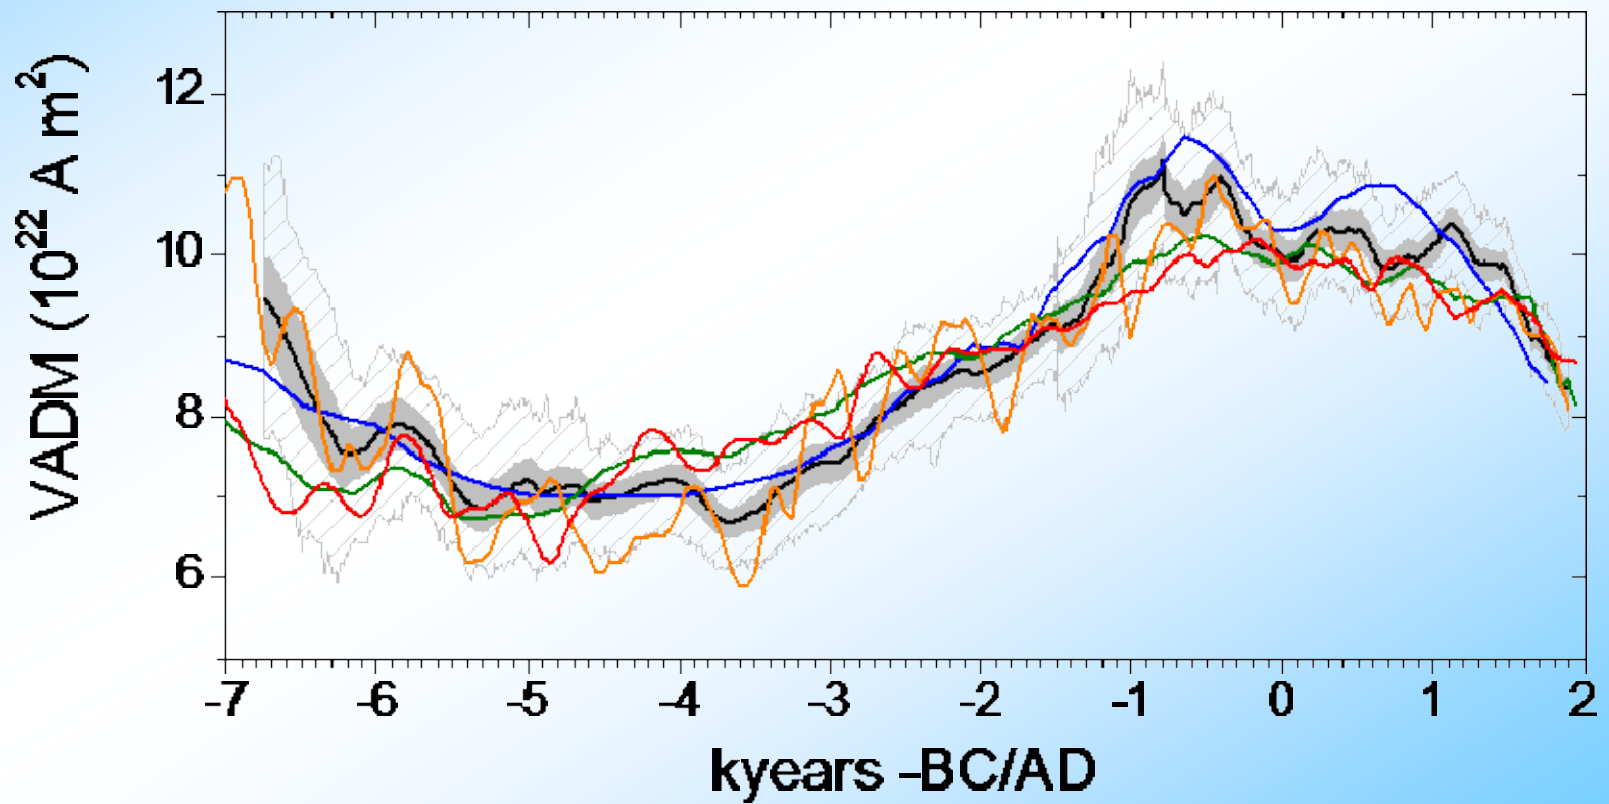

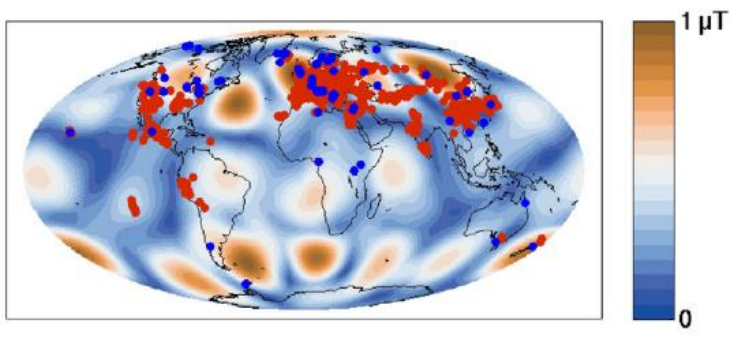

Production model

Kovaltsov, Mishev & Usoskin (EPSL, 2012)

- Full range of GCR energy (0.01-1000 GeV)
- Heavier species included explicitly

Paleomagnetic models

cosmogenic ^{14}C and ^{10}Be

$\text{CO}_2 \rightarrow$ carbon cycle \rightarrow tree rings

- Effective CR energy is ~ 3 GeV/nucleon;
- mean altitude: upper tropo, low stratosphere;
- measurements: normalized $^{14}\text{C}/^{12}\text{C}$ ratio

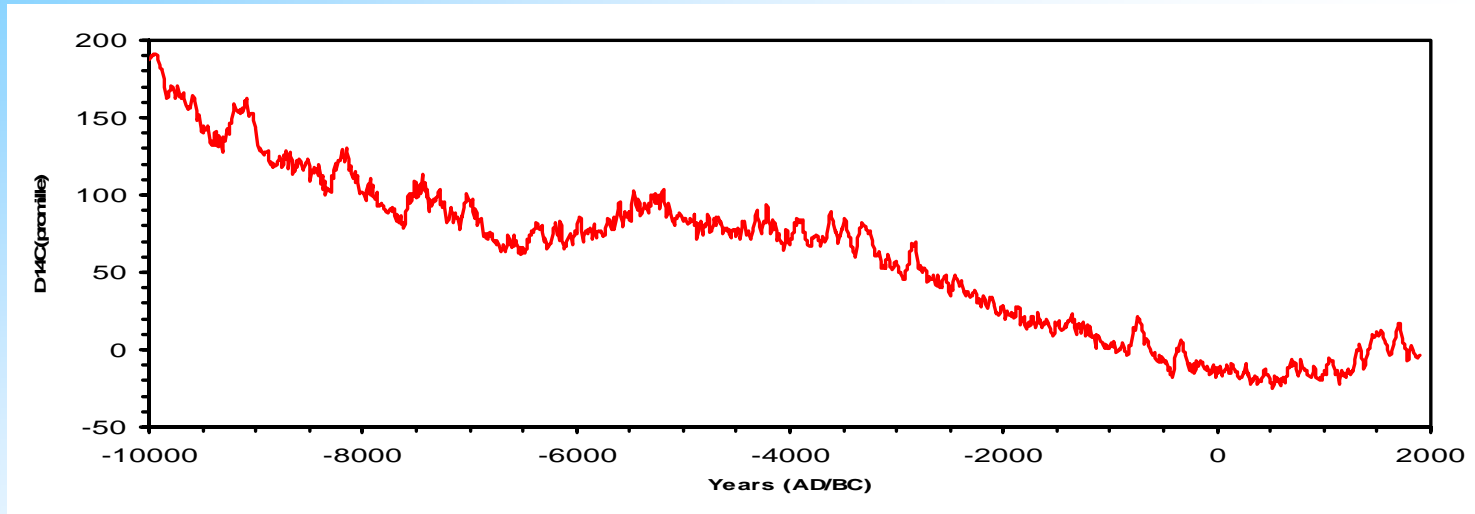

aerosols \rightarrow fall out

- Effective CR energy is 1–2 GeV/nucleon;
- mean altitude: upper tropo, lower stratosphere;
- measurements: abundance

Radiocarbon data

Bern3D-LPX model

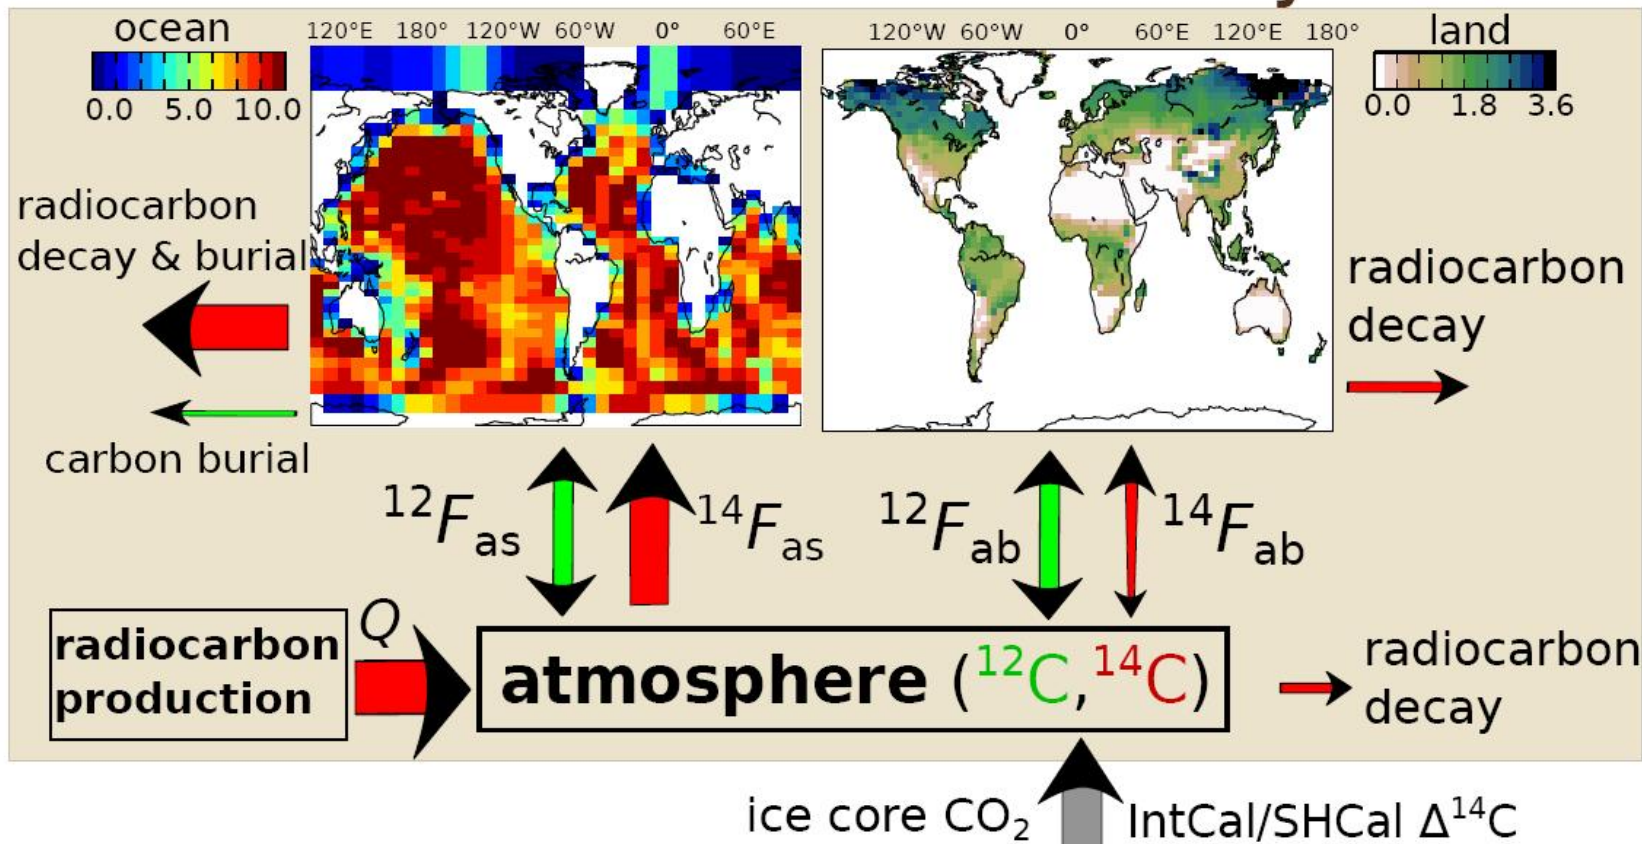

energy & moisture balance model

temperature
precipitation
irradiance

← GHGs radiative forcing
SO₄ aerosols forcing
ice-sheet extent/albedo
orbital parameters

carbon cycle model

Atmospheric transport of ^{10}Be

(a) Annual mean wet ^{10}Be deposition (10^{-27} kg/m²/s)

Annual Mean Wet ^{10}Be Precipitation- Field et al (JGR, 2006)

Quality of the model

Long-term reconstructions

Reconstructions of the modulation potential ϕ :

¹⁴C-based reconstruction (Solanki et al., Nature, 2004; Usoskin et al., A&A, 2007);

Composite ¹⁰Be (Steinhilber et al., PNAS, 2012)

Sunspot activity during the Holocene

27 Grand minima
19 Grand maxima
can be identified:

Minima (1880 yr – 17%)

Maxima (1030 yr – 9%)

No clear periodicity, but :

- clustering of Grand minima with 2000-2400 yr;
- ~200-yr periodicity inside the clusters;
- no apparent periodicity for Grand maxima;

SN reconstruction since 1000 BC

Observational facts

- Solar activity depicts a great deal of variability, from Grand minima to Grand maxima;
- Recent solar activity (1940-2008) was an Grand maximum, but now we are facing regular or weak activity;
- The Sun spends $\sim 3/4$ of the time at moderate activity, $1/6$ in a Grand minimum and $1/10$ in a Grand maximum state. The recent solar activity was a Grand maximum.
- Occurrence of Grand minima/maxima is not a result of long-term cyclic variations but is defined by stochastic / chaotic processes.

Summary: Knowns

- The main source of CR variability on time scales from days to millennia is the solar magnetic activity.
- CR variations, via cosmogenic isotopes, is the only source of information on the solar/heliospheric activity in the distant past.
- Solar activity varied essentially from the regular stable mode – from Grand minima to Grand maxima.
- The Grand maximum is over, the current "weak" solar activity level is in fact "normal" one.

Unknowns

- The very long-term (multi-millennial) trend in SA may be uncertain.
- The main uncertainty is the geomagnetic field in the past (before 3000 BC).
- Long-term climate variability (ocean circulation and large-scale atmospheric dynamic) may add uncertainties.
- Some Grand minima and Grand maxima can be less certain because of the noisy data, particularly ^{10}Be .
- These uncertainties can be constrained by using multi-proxy records-

THANK YOU !
